Principal Component Analysis-Based Broadband Hybrid Precoding for Millimeter-Wave Massive MIMO Systems

Yiwei Sun, Zhen Gao, Member, IEEE, Hua Wang, Member, IEEE, Byonghyo Shim, Senior Member, IEEE, Guoqiang Mao, Senior Member, IEEE, Guoqiang Mao, Fellow, IEEE, and Fumiyuki Adachi, Life Fellow, IEEE

Abstract—Hybrid analog-digital precoding is challenging for broadband millimeter-wave (mmWave) massive MIMO systems, since the analog precoder is frequency-flat but the mmWave channels are frequency-selective. In this paper, we propose a principal component analysis (PCA)-based broadband hybrid precoder/combiner design, where both the fully-connected array and partially-connected subarray are investigated. Specifically, we first design the hybrid precoder/combiner for fully-connected array and fixed subarray based on PCA, whereby a low-dimensional frequency-flat precoder/combiner is acquired based on the optimal high-dimensional frequency-selective precoder/combiner. Meanwhile, the near-optimality of our proposed PCA approach is theoretically proven. Moreover, for the adaptive subarray, a low-complexity shared agglomerative hierarchical clustering algorithm is proposed to group the antennas for the further improvement of spectral efficiency (SE) performance. Besides, we theoretically prove that the proposed antenna grouping algorithm is only determined by the slow time-varying channel parameters in the large antenna limit. Simulation results demonstrate the superiority of the proposed solution over state-of-the-art schemes in SE, energy efficiency (EE), bit-error-rate performance, and the robustness to time-varying channels. Our work reveals that the EE advantage of adaptive subarray over fully-connected array is obvious for both active and passive antennas, but the EE advantage of fixed subarray only holds for passive antennas.

Index Terms—Hybrid precoding, massive MIMO, OFDM, millimeter-wave, adaptive subarray, energy efficiency.

I. INTRODUCTION

Millimeter-WAVE (mmWave) communication has been conceived to be a key enabling technology for the next-generation communications, since it can provide Gbps data rates by leveraging the large transmission bandwidth [1]–[7]. To combat the severe path loss in mmWave channels, a large number of antennas are usually employed at both the base stations (BS) and the mobile stations for beamforming [8]. However, a large number of antennas could lead to the severe hardware cost and power consumption if each antenna requires a radio frequency (RF) chain as in conventional fully-digital MIMO systems. To overcome this problem, hybrid MIMO has been emerging to trade off hardware cost with the spectral efficiency (SE) and energy efficiency (EE) [11]–[15]. This tradeoff depends on the specific hybrid MIMO architectures, which includes the fully-connected array (FCA) and partially-connected subarray (PCS), and the latter can be further categorized into the fixed subarray (FS) and adaptive subarray (AS) as depicted in Fig. 1 [16]. Nevertheless, how to design the hybrid precoding over broadband channels is challenging, as the RF precoding is frequency flat and has the constant-modulus constraint (CMC) [23]. Therefore, it is of great importance to design an efficient broadband hybrid precoder/combiner for mmWave massive MIMO systems.

A. Related Work

Narrowband hybrid precoding has been investigated in [11], [12], [17]–[21]. Specifically, a compressive sensing (CS)-based hybrid precoding was proposed in [17], where the channel sparsity was exploited with the aid of orthogonal matching pursuit (OMP) algorithm. To reduce the computational complexity, a low-complexity CS-based beamspace
hybrid precoding was developed in [18]. To improve the EE, an iterative analog precoding was designed for FS [19], but it failed to consider the digital precoding. Moreover, a constant envelope hybrid precoding scheme was proposed, where the hybrid precoding was designed under the per-antenna constant envelope constraints [11]. Additionally, the codebook-based scheme, the hybrid block diagonal scheme, and the heuristic scheme were respectively proposed in [12], [20], and [21] for multi-user MIMO. In contrast to the described prior art, hybrid solutions with significantly different analog architectures have also been explored in [9], [10], which provide benefits of reduced hardware cost and channel estimation overhead. However, [11], [12], [17]–[21] only assumed the flat fading channels.

To effectively combat the time dispersive channels, several elegant broadband hybrid precoding solutions have been proposed in [22]–[25]. Most of them adopted OFDM so that the broadband frequency-selective fading channels were converted into multiple parallel narrowband frequency-flat fading channels. To be specific, a hybrid precoding scheme has been proposed in [22] to support single stream transmission in MIMO-OFDM system, where the optimal beam pair was exhaustively searched from a codebook predefined for FS. To reduce the computational complexity, the limited-feedback codebook based broadband hybrid precoder has been proposed for fully-connected array (FCA) [23]. Moreover, by exploiting the channel correlation information among different subcarriers, a broadband hybrid precoding was proposed, where both FCA and PCS were investigated [24]. However, [23] did not specify the combiner design at the receiver, and [24] assumed the fully-digital array at the receiver. Note that in [24], although a greedy algorithm was proposed to group the antennas for AS, this method could suffer from the poor performance due to the unbalanced antenna grouping. Besides, by proving the dominant subspaces of frequency domain channel matrices at different subcarriers are equivalent, [25] has theoretically revealed the optimality of the frequency-flat precoding. However, this conclusion was based on the ideal sparse channels by assuming the discrete angles of arrival/departure (AoA/AoD), and the specific precoder/combiner solution was not explicitly provided.

B. Our Contributions

In this paper, we propose a broadband hybrid precoding for mmWave massive MIMO systems, where both FCA and PCS are investigated. First, the hybrid precoder/combiner for FCA is designed based on the principal component analysis (PCA), whereby a near-optimal low-dimensional analog precoder/combiner is acquired from the optimal high-dimensional fully-digitally precoder/combiner. Furthermore, this PCA-based approach is generalized to PCS. Besides, for the AS, a low-complexity shared agglomerative hierarchical clustering (shared-AHC) algorithm is proposed to group the antennas adapted to the channels for the further improved SE performance. The contributions of this paper are summarized as follows:

- **Near-optimal PCA-based hybrid precoder/combiner design.** Based on the framework of PCA (weighted PCA), we design the analog precoder (combiner) at the transmitter (receiver) according to the optimal fully-digital precoder (combiner). By contrast, state-of-the-art solutions usually only design the hybrid precoder, nevertheless, the hybrid combiner was not specified and the BER performance was not evaluated [22]–[25]. We theoretically prove the near-optimality of our proposed PCA-based solution, whose SE and BER advantages over state-of-the-art solutions are also verified by simulations.

- **Low-complexity shared-AHC algorithm to group antennas for AS.** The optimal antenna grouping for AS requires the exhaustive search, which suffers from the prohibitively high computational complexity. To solve this problem, we formulate the antenna grouping problem as the clustering problem in machine learning, and further propose a low-complexity shared-AHC algorithm. Meanwhile, we prove that the antenna grouping strategy based on the proposed shared-AHC algorithm is only determined by the slow time-varying channel parameters in the large antenna limits. By comparison, the existing solution [24] only considered the antenna grouping at the transmitter (TX), and it could lead to the extremely unbalanced antenna grouping case that no antenna was assigned to one RF chain.

- **EE performance evaluation in practical passive/active antennas.** Passive and active antennas have the different array architectures, which result in the different numbers of power-consuming electronic elements (e.g., power amplifiers). EE analysis in prior work [28]–[30], [45] did not distinguish the passive and active antennas. By contrast, we consider the practical passive/active antennas for EE performance analysis. Our work demonstrates that the EE advantage of AS over FCA is overwhelming for both active and passive antennas, while the EE advantage of FS over FCA can only be observed for passive antennas.

The rest of this paper is organized as follows. The system model is introduced in Section II. The proposed PCA-based hybrid precoder/combiner for FCA is presented in Section III. The proposed PCA-based hybrid precoder/combiner for PCS and the proposed shared-AHC-based antenna grouping for AS are presented in Section IV. In Section V, we evaluate the system performance. Finally, we conclude this paper in Section VII. This paper was presented in part at the IEEE GLOBECOM’18 [43], [44]. Except for the work presented in [43], [44], the unique contribution of this paper is the...
expansion of the PCS structure on hybrid combiner and the evaluation of the performance, including the EE performance of the system, the computational complexity of the antenna grouping algorithm, the robustness of antenna grouping algorithm to time-varying channel, and the robustness to channel perturbation.

Notations: Following notations are used throughout this paper. $\mathbf{A}$ is a matrix, $\mathbf{a}$ is a vector, $a$ is a scalar, and $A$ is a set. Conjugate transpose and transpose of $\mathbf{A}$ are $\mathbf{A}^H$ and $\mathbf{A}^T$, respectively. The $(i,j)$th entry of $\mathbf{A}$ is $[\mathbf{A}]_{i,j}$, $\mathbf{A}(:,:) = [\mathbf{A}]_{i,:)$. $\mathbf{A}(:,j)$ denotes the $j$th row $(j$th column) of $\mathbf{A}$, sub-matrix $[\mathbf{A}]_{i,:j} = [\mathbf{A}]_{(i,:)j}$ consists of the $i$th row to $i$th rows $(j$th to $j$th columns) of $\mathbf{A}$, and sub-matrix $[\mathbf{A}]_{i,:j} = [\mathbf{A}]_{i,i,:j}$ consists of the $i$th row to $i$th rows and $j$th to $j$th columns of $\mathbf{A}$. Frobenius norm, $\ell_2$-norm, and determinant are denoted by $\|\cdot\|_F$, $\|\cdot\|_2$, and $\det()$, respectively. card($\mathcal{A}$) is the cardinality of a set $\mathcal{A}$, $\mathcal{A} \setminus \mathcal{B}$ is $\{x | x \in \mathcal{A} \land x \notin \mathcal{B}\}$. $\mathcal{I}_N$ denotes an identity matrix with size $N \times N$. The $i$th largest singular value of a matrix $\mathbf{A}$ is defined as $\lambda_i(\mathbf{A})$. $(\cdot)^+$ denote $(\cdot)^*=\mathbf{A}^H$ if $a > 0$, otherwise $(\cdot)^+=0$. $\text{blkdiag}(\mathbf{a}_1, \ldots, \mathbf{a}_K)$ is a block diagonal matrix with $\mathbf{a}_1, (1 \leq i \leq K)$ on its diagonal blocks. Finally, $\mathcal{Col}A$ is the column space of the matrix $\mathbf{A}$, and $(\mathcal{Col}A)^\perp$ is the orthogonal complement space of $\mathcal{Col}A$.

II. SYSTEM MODEL

We consider a downlink mmWave massive MIMO system with perfect synchronization (this can be achieved by efficient algorithms like [26], [46]) as shown in Fig. 2, where both the BS and the user employ the uniform planar array (UPA), and OFDM is adopted to combat the frequency-selective fading channels. The BS is equipped with $N_t = N_t^v \times N_t^h$ antennas and $N_t^\text{RF} \ll N_t$ RF chains, where $N_t^v$ and $N_t^h$ are the numbers of vertical and horizontal transmit antennas, respectively. The user is equipped with $N_r = N_r^v \times N_r^h$ antennas and $N_r^\text{RF} \ll N_r$ RF chains, where $N_r^v$ and $N_r^h$ are the numbers of vertical and horizontal receive antennas, respectively. In the downlink, the received signals of the $k$th subcarrier at the user are [17]

$$r[k] = (\mathbf{W}_\text{RF} \mathbf{W}_\text{BB}[k])^H (\mathbf{H}[k] \mathbf{F}_\text{RF} \mathbf{F}_\text{BB}[k] x[k] + \mathbf{n}[k]),$$

$$1 \leq k \leq K,$$  

where $K$ is the number of subcarriers, $\mathbf{F}_\text{BB}[k] \in \mathbb{C}^{N_t \times N_t}$, $\mathbf{F}_\text{RF} \in \mathbb{C}^{N_r \times N_t^\text{RF}}$, $\mathbf{W}_\text{BB}[k] \in \mathbb{C}^{N_t \times N_t}$, $\mathbf{W}_\text{RF} \in \mathbb{C}^{N_r \times N_t^\text{RF}}$, $\mathbf{H}[k] \in \mathbb{C}^{N_r \times N_t}$, $x[k] \in \mathbb{C}^{N_t \times 1}$, and $\mathbf{n}[k] \in \mathbb{C}^{N_r \times 1}$ are the digital precoder, analog precoder, digital combiner, analog combiner, frequency-domain channel matrix, transmitted signal, and additive white Gaussian noise (AWGN) associated with the $k$th subcarrier, respectively, and $N_r$ is the number of data streams. $\mathbf{n}[k] \sim \mathcal{CN}(0, \sigma^2 \mathbf{I}_{N_r})$ and $x[k]$ satisfies $\mathbb{E}[x[k]x^H[k]] = \mathbf{I}_{N_t}$. Here $\mathbf{H}[k] = \sum_{d=0}^{D-1} \mathbf{H}[d] e^{-j \frac{2 \pi d}{K}}$, where $D$ is the maximum delay spread of the discretized channels, and $\mathbf{H}[d] \in \mathbb{C}^{N_r \times N_t}$ is the delay-domain channel matrix of the $d$th delay tap. We consider the clustered channel model [17], where the channel comprises $N_{cl}$ clusters of multipaths with $N_{my}$ rays in each cluster. Thus, the delay-domain channel matrix is

$$\mathbf{\hat{H}}[d] = \sum_{i=1}^{N_{cl}} \sum_{l=1}^{N_{my}} \hat{p}_{i,l}[d] \mathbf{a}_i(\hat{\phi}_{i,l}^v, \hat{\theta}_{i,l}^h) \mathbf{a}_i^H(\hat{\phi}_{i,l}^v, \hat{\theta}_{i,l}^h),$$

where $\hat{p}_{i,l}[d] = \sqrt{N_t N_r/\sum_{d'=0}^{D-1} \hat{p}_{i,l}[d'] e^{-j \frac{2 \pi d}{K}}}$ is the delay-domain channel coefficient, $\tau_{i,l}$, $\alpha_{i,l}$, and $p$ are the delay, the complex path gain, and the pulse shaping filter for $T_s$-spaced signaling, respectively. Thus the frequency-domain channel coefficient is $p_{i,l}[k] = \sum_{d=0}^{D-1} \hat{p}_{i,l}[d] e^{-j \frac{2 \pi d k}{K}}$. In (2), $\mathbf{a}_i(\hat{\phi}_{i,l}^v, \hat{\theta}_{i,l}^h)$ and $\mathbf{a}_i(\hat{\phi}_{i,l}^v, \hat{\theta}_{i,l}^h)$ are the steering vectors of the $i$th path in the $i$th cluster at the TX and receiver (RX), respectively, where $\hat{\phi}_{i,l}^v (\hat{\theta}_{i,l}^h)$ and $\hat{\theta}_{i,l}^v (\hat{\phi}_{i,l}^h)$ are the azimuth and elevation angles of the $i$th ray in the $i$th cluster for AoDs (AoAs). The steering vector of the $i$th ray in the $i$th cluster for AoD is $\mathbf{a}_i(\hat{\phi}_{i,l}^v, \hat{\theta}_{i,l}^h) = e^{j \Omega_{i,l}^v} e^{j \Omega_{i,l}^h}$, where $e^{j \Omega_{i,l}^v} = \sqrt{N_t} \left[ e^{-j 2 \pi \Omega_{i,l}^v} e^{-j 2 \pi \Omega_{i,l}^v} \ldots e^{-j 2 \pi \Omega_{i,l}^v} \right]$, $\Omega_{i,l}^v = \frac{1}{\lambda_v} \left[ \frac{1}{\lambda_v} \right]$, $\Omega_{i,l}^v = \cos(\phi_{i,l}^v) \sin(\phi_{i,l}^v) \lambda_v$, $\lambda_v$ is the carrier wavelength, and $d_h = \frac{\lambda_v}{d_x}$, $d_v = \frac{\lambda_v}{d_y}$ denote the horizontally and vertically antenna spacing, respectively [8]. Similarly, the receiving steering vectors are $\mathbf{a}_i(\hat{\phi}_{i,l}^v, \hat{\theta}_{i,l}^h) = e^{-j \frac{2 \pi (\nu \hat{\phi}_{i,l}^v + \psi_{i,l}^v) d_x}{\lambda_v}} e^{-j \frac{2 \pi (\nu \hat{\theta}_{i,l}^h + \psi_{i,l}^h) d_y}{\lambda_v}}$, $1 \leq l \leq N_{my}$, where $\psi_{i,l}^v = \sin(\phi_{i,l}^v) \sin(\phi_{i,l}^v) d_h$, and $\psi_{i,l}^h = \cos(\phi_{i,l}^h) d_v$.

The achievable SE for the mmWave MIMO-OFDM system can be expressed as [23]

$$R = \frac{1}{K} \sum_{k=1}^{K} \log_2 (\det(\mathbf{I} + R_n^{-1}[k] \mathbf{W}_\text{BB}[k] \mathbf{W}_\text{RF} \mathbf{H}[k] \mathbf{F}_\text{RF} \mathbf{F}_\text{BB}[k] \mathbf{F}_\text{RF}^H \mathbf{F}_\text{BB}[k] \mathbf{W}_\text{RF} \mathbf{W}_\text{BB}[k])),$$

where $R_n[k] = \sigma^2 \mathbf{W}_\text{BB}[k] \mathbf{W}_\text{RF} \mathbf{W}_\text{RF} \mathbf{W}_\text{BB}[k]$, $\sum_{k=1}^{K} || \mathbf{F}_\text{RF} \mathbf{F}_\text{BB}[k] ||_F^2 = K N_t$, $\mathbf{F}_\text{RF}, \mathbf{F}_\text{BB}[k] \in \mathbf{F}_\text{RF} \in \mathbb{C}^{N_r \times 1}$, $\mathbf{W}_\text{RF} \in \mathbb{C}^{N_r \times N_r}$, and $\mathbf{W}_\text{BB}[k] \in \mathbb{C}^{N_t \times 1}$ are respectively the sets of feasible RF precoder and combiner satisfying the CMC for each entry. Note that our work is distinctly different from the previous work [24], which considered the hybrid precoder but the fully-digital combiner. In this paper, we consider the hybrid MIMO architecture at both the TX and RX. Given full channel state information (CSI) at both TX and RX by using state-of-art efficient channel estimation solutions [1], [4], [5], [7], [27],
our goal is to design the hybrid precoder and combiner that maximize the SE. Since the sum rate $R$ is a function of variables $(\mathbf{F}_{RF}, \{\mathbf{F}_{BB}[k]\}_{k=1}^{K}, \mathbf{W}_{RF}, \{\mathbf{W}_{BB}[k]\}_{k=1}^{K})$, it is computationally inefficient to jointly optimize the sum rate. How to solve this intractable problem will be detailed as follows.

III. PCA-BASED HYBRID PRECODER/COMBINER FOR FCA

In this section, we will propose the hybrid precoder/combiner design for mmWave massive MIMO systems based on FCA (weighted FCA), whereby the frequency-flat RF precoder (combiner) can be acquired from the optimal fully-digital frequency-selective precoder (combiner).

A. PCA-Based Hybrid Precoder Design at TX

We first design the hybrid precoder by solving the following optimization problem

$$
\begin{align*}
(\mathbf{F}_{RF}^{\text{opt}}, \{\mathbf{F}_{BB}[k]\}_{k=1}^{K}) & = \max_{\mathbf{F}_{RF}, \{\mathbf{F}_{BB}[k]\}_{k=1}^{K}} \log_2(\det(\mathbf{I}_N + \frac{1}{\sigma_n^2} \mathbf{H}[k] \mathbf{F}_{RF} \mathbf{F}_{RF}^H \mathbf{H}[k])) \\
& \text{s.t. } \mathbf{F}_{RF}, \mathbf{F}_{BB}[k] \in \mathbb{F}_K, 1 \leq i \leq N_t^{RF}, \sum_{k=1}^{K} ||\mathbf{F}_{RF} \mathbf{F}_{BB}[k]||_F^2 = K N_s.
\end{align*}
$$

The joint optimization of $\mathbf{F}_{RF}$ and $\{\mathbf{F}_{BB}[k]\}_{k=1}^{K}$ in (4) is difficult due to the coupling between $\mathbf{F}_{RF}$ and $\{\mathbf{F}_{BB}[k]\}_{k=1}^{K}$. This motivates us to design $\mathbf{F}_{RF}$ and $\{\mathbf{F}_{BB}[k]\}_{k=1}^{K}$ separately. We consider $\tilde{\mathbf{F}}_{BB}[k] = (\mathbf{H}^H \mathbf{F}_{RF}^H)^{-1} \mathbf{F}_{BB}[k]$ to be the equivalent baseband precoder, so that (4) can be rewritten as

$$
\begin{align*}
& \max_{\mathbf{F}_{RF}, \{\mathbf{F}_{BB}[k]\}_{k=1}^{K}} \log_2(\det(\mathbf{I}_N + \frac{1}{\sigma_n^2} \mathbf{H}[k] \mathbf{F}_{RF} \mathbf{F}_{RF}^H \mathbf{H}[k])) \\
& \times ||\mathbf{F}_{BB}[k]||_F^2 ||(\mathbf{H}^H \mathbf{F}_{RF}^H)^{-1/2} \mathbf{F}_{BB}[k]||^2 \\
& \text{s.t. } \mathbf{F}_{RF}, \mathbf{F}_{BB}[k] \in \mathbb{F}_K, 1 \leq i \leq N_t^{RF}, \sum_{k=1}^{K} ||\mathbf{F}_{BB}[k]||_F^2 = K N_s.
\end{align*}
$$

To solve the optimization problem (5), we first investigate the optimal solution of $\{\mathbf{F}_{BB}[k]\}_{k=1}^{K}$. Specifically, we consider the singular value decomposition (SVD) of $\mathbf{H}[k]$ at the $k$th subcarrier

$$
\mathbf{H}[k] = \mathbf{U}[k] \mathbf{\Sigma}[k] \mathbf{V}^H[k],
$$

and the SVD of the matrix $\mathbf{\Sigma}[k] \mathbf{V}^H[k] \mathbf{F}_{RF} (\mathbf{F}_{RF}^H \mathbf{F}_{RF})^{-1/2} = \mathbf{U}[k] \mathbf{\Sigma}[k] \mathbf{V}^H[k]$. Therefore, the optimal equivalent baseband precoder is $\tilde{\mathbf{F}}_{BB}[k] = [\mathbf{V}[k]_{1:i:N_s}] \mathbf{A}[k] \in \mathbb{C}^{N_r \times N_s}$, and thus the optimal baseband precoder $\mathbf{F}_{BB}[k]$ can be expressed as

$$
\begin{align*}
\mathbf{F}_{BB}[k] & = (\mathbf{F}_{RF}^H \mathbf{F}_{RF})^{-1/2} \tilde{\mathbf{F}}_{BB}[k] \\
& = (\mathbf{F}_{RF}^H \mathbf{F}_{RF})^{-1/2} [\mathbf{V}[k]_{1:i:N_s}] \mathbf{A}[k],
\end{align*}
$$

where $\mathbf{A}[k] \in \mathbb{C}^{N_s \times N_s}$ is the water-filling solution matrix, i.e.,

$$
[\mathbf{A}[k]]^2_{i,i} = (\mu - \sigma_n^2 / \mathbb{E}[\mathbf{\Sigma}[k]]^2_{i,i})^+, 1 \leq i \leq N_s, 1 \leq k \leq K.
$$

\begin{algorithm}
1. **Algorithm 1 PCA-Based RF Precoder Design**

**Input:** $\{\mathbf{F}_{RF}^{\text{opt}}[k]\}_{k=1}^{K}, \mathbb{F}_K, \mathbb{F}_N, N_t, N_q$.

**Output:** $\mathbf{F}_{RF}$.

1. $\mathbf{F}_{RF}^{\text{opt}} = [\mathbf{F}_{RF}^{\text{opt}}[1] | \mathbf{F}_{RF}^{\text{opt}}[2] \cdots | \mathbf{F}_{RF}^{\text{opt}}[K]]$ (Here $\mathbf{F}_{RF}^{\text{opt}}[k] = [\mathbf{U}[k]_{1:i:N_s}] \mathbf{H}[k]$).

2. Apply SVD to $\mathbf{F}_{RF}^{\text{opt}}$, i.e., $\mathbf{F}_{RF}^{\text{opt}} = \mathbf{U}_F \mathbf{\Sigma}_F \mathbf{V}_F^H$, where $\mathbf{U}_F$ corresponds to the principal components

3. Extract the phases by using an intermediate variable $\mathbf{F}_{\text{int}} = \frac{1}{\sqrt{N_t}} \exp(j \angle(\mathbf{F}_{RF}^{\text{opt}}[\cdot],1:N_t^{RF}))$.

4. Quantization by $\mathbf{F}_{RF} = \frac{1}{\sqrt{N_t}} \exp(j 2\pi \text{round}(\frac{2Q \angle(\mathbf{F}_{\text{int}},1:N_t^{RF})}{2\pi}))$

Besides, given the practical RF phase shifters with the quantization bit $Q$ [33], the phase shifter values can only come from the set $Q = \{0, 2\pi, \cdots, 2\pi(2^Q-1)\}$. Therefore, this quantization processing will be performed by searching for the element from $Q$ according to the minimum Euclidean distance from $\angle(\mathbf{F}_{RF}[\cdot],1)$.

Water filling is not considered for the ease of analysis, and it can be adopted to maximize the sum rate according to [25].
Note that our PCA-based approach is essentially different from that proposed in [24], whose RF precoder is acquired from the eigenvectors of channel covariance matrix $R_{\text{cov}} = \frac{1}{K} \sum_{k=1}^{K} H^H[k]H[k]$. By contrast, the RF precoder in our solution is obtained by solving the principal components or basis for the common column space of channel matrices $\{H[k]\}_{k=1}^{K}$ at all subcarriers, where the processing is listed in steps 1~2 of Algorithm 1. Simulation results further confirm the better performance of our solution than that proposed in [24] for hybrid MIMO systems. However, the channel covariance matrix based design in [24] may have a lower channel estimation overhead than the PCA solution presented here, a detailed analysis of which is beyond the scope of this paper.

### B. PCA-Based Hybrid Combiner Design at RX

Based on the designed $F_{\text{RF}}$ and $\{F_{\text{BB}}[k]\}_{k=1}^{K}$, we further design the hybrid combiner to maximize $\sum_{k=1}^{K} ||x[k] - r[k]||_2^2$. Specifically, the optimal fully-digital combiner is the minimum mean square error (MMSE) combiner, i.e., $W_{\text{opt}}^{H}F_{\text{RF}} = W_{\text{MMSE}}^{H}[k]$, which can be expressed as

$$W_{\text{MMSE}}^{H}[k] = F_{\text{RF}}^{H}[k]F_{\text{RF}}^{H}H_{\text{RF}}^{H}[k]\sum_{k=1}^{K} W_{\text{RF}}F_{\text{BB}}[k]F_{\text{BB}}^{H}[k]$$

(10)

Defining the signal at the receive antennas as $y[k] \in \mathbb{C}^{N_r \times 1}$ ($1 \leq k \leq K$), we formulate the combiner design problem as the following optimization problem,

$$\left(\min_{W_{\text{RF}}} ||x[k] - W_{\text{RF}}F_{\text{RF}}y[k]||_2 \right)$$

(11)

Note that if the CMC in (11) is removed, the solution to (11) is the optimal fully-digital MMSE combiner (10). The objective function in (11) can be further written as

$$\sum_{k=1}^{K} \mathbb{E}[||x[k] - W_{\text{RF}}F_{\text{RF}}y[k]||_2]$$

$$= \sum_{k=1}^{K} \mathbb{E}[||x[k] - W_{\text{BB}}^{H}[k]W_{\text{RF}}y[k]||_2]$$

$$= \sum_{k=1}^{K} \mathbb{E}[||x[k] - W_{\text{RF}}F_{\text{RF}}y[k]||_2]$$

$$\leq \sum_{k=1}^{K} \mathbb{E}[||x[k] - W_{\text{RF}}F_{\text{RF}}y[k]||_2]$$

(12)

Since the optimization variables in (11) are $W_{\text{RF}}$ and $\{W_{\text{BB}}[k]\}_{k=1}^{K}$, terms unrelated to $W_{\text{RF}}$ and $\{W_{\text{BB}}[k]\}_{k=1}^{K}$ will not affect the solution. By adding the independent term $\sum_{k=1}^{K} \mathbb{E}[||x[k] - W_{\text{RF}}F_{\text{RF}}y[k]||_2]$ to the objective function (12), the optimization problem (11) can be further expressed as

$$\min_{w_{\text{RF}}, \{w_{\text{MMSE}}[k]\}_{k=1}^{K}} \sum_{k=1}^{K} \mathbb{E}[||x[k] - W_{\text{RF}}F_{\text{RF}}y[k]||_2^2]$$

$$\leq \sum_{k=1}^{K} \mathbb{E}[||x[k] - W_{\text{RF}}F_{\text{RF}}y[k]||_2^2]$$

(13)

For the FS, according to Lemma 1, the optimization problem (9) can be simplified as

$$\max_{\text{RF}} \sum_{k=1}^{K} ||W_{\text{RF}}F_{\text{RF}}y[k]||_2^2$$

subject to $\{f_{\text{RF}}[k]\}_{k=1}^{K} \in F_{\text{RF}}$, (15), $f_{\text{RF}}[k] \in F_{\text{RF}}$, $\forall l$,

(16)

where $F_{\text{RF}}$ is a set of feasible RF precoder satisfying the CMC, and the optimal fully-digital precoder $F_{\text{RF}}^{\text{opt}}[k] = \mathbb{V}[k], \forall l, k \in N_{c} \times N_{s}$ can be expressed as the following block matrix form

$$F_{\text{RF}}^{\text{opt}}[k] = \begin{bmatrix} F_{\text{opt},S_{t}}^{H}[k] & \cdots & F_{\text{opt},S_{N_{r}}}^{H}[k] \end{bmatrix}$$

(17)
Here $F_{\text{opt},S}[k] \in \mathbb{C}^{N_{\text{RF}} \times N_r}$, $\forall k$. To solve (16), we use the following proposition.

**Proposition 3:** For $S$, given $F_S = [F_{\text{opt},S}[1] \cdots F_{\text{opt},S}[K]]$, the sub-optimal $F_{\text{RF}}$ to (16) is $F_{\text{RF}} = \text{blkdiag} (F_{\text{RF},S_1}, \cdots, F_{\text{RF},S_{N_{\text{RF}}}})$, where $F_{\text{RF},S} = \frac{1}{\sqrt{N_{\text{RF}}}} \exp(j \angle (u_{S,1}))$, $u_{S,1} \in \mathbb{C}^{N_{\text{RF}} \times 1}$ is the right singular vector of the largest singular value of $F_S$, $\forall l$.

**Proof:** By substituting (15) and (17) into the objective function (16), we can further have

$$
\sum_{k=1}^{K} \| F_{\text{opt},H}^T [k] F_{\text{RF}} \|_F^2 = \sum_{k=1}^{K} \left[ \sum_{l=1}^{N_{\text{RF}}} \left| F_{\text{opt},H}^T [k][F_{\text{RF},S}]_l \right| \right]^2_{\| F_{\text{RF},S} \|_F^2} = \sum_{l=1}^{N_{\text{RF}}} \lambda_1^2 (F_{S,l}) \leq \sum_{k=1}^{K} \lambda_1^2 (F_{S,k}) \leq \sum_{k=1}^{K} \lambda_1^2 (F_{S,k}),
$$

where $\lambda_1 (F_S)$ means the largest singular value of matrix $F_S$. The maximum value can only be obtained if $F_{\text{RF},S} = \frac{1}{\sqrt{N_{\text{RF}}}} \exp(j \angle (u_{S,1}))$, where $u_{S,1} \in \mathbb{C}^{N_{\text{RF}} \times 1}$ is the left singular vector of the largest singular value of the matrix $F_S$.

By taking quantization of phase shifters into account, the final $F_{\text{RF}}$ is $F_{\text{RF},S} = \frac{1}{\sqrt{N_{\text{RF}}}} \exp(j \angle (u_{S,1}))$, $\forall l$. Meanwhile, $\{F_{\text{BB}}[k]\}_{k=1}^{K}$ can be obtained according to (7).

At the RX, we consider the subset of antenna indices connected to the $l_{th}$ RF chain as $T_l = \{(l-1)N_{\text{sub}} + 1, \cdots, lN_{\text{sub}}\}$, $\forall l$, where card($T_l$) = $N_{\text{sub}} = N_r/N_r \in \mathbb{Z}$ for ease of analysis. Similar to the TX, we have $W_{\text{RF}} = \text{blkdiag}(w_{\text{RF},T_1}, \cdots, w_{\text{RF},T_{N_{\text{RF}}}})$ and $W_{\text{BB}}[k] = [w_{\text{BB},T_1}[k] \cdots w_{\text{BB},T_{N_{\text{RF}}}}[k]] H \in \mathbb{C}^{N_r \times N_r}$, where $w_{\text{BB},T_l}[k] \in \mathbb{C}^{N_r \times 1}$ is the baseband combiner of the $l_{th}$ receive subarray. Hence $W_{\text{RF}}W_{\text{BB}}[k] = [w_{\text{RF},T_1}[k] \cdots w_{\text{RF},T_{N_{\text{RF}}}}[k]] H \in \mathbb{C}^{N_r \times N_r}$. Moreover, consider the effective channel

$$
H_{\text{eff}}[k] = H[k] F_{\text{RF}} F_{\text{BB}}[k],
$$

the received signal $y[k] = [(y_{T_1}[k]) T \cdots (y_{T_{N_{RF}}}[k]) T]^T \in \mathbb{C}^{N_r \times 1}$ with $y_{T_l}[k] \in \mathbb{C}^{N_r \times 1}$, the effective channel

$$
H_{\text{eff}}[k] = [(H_{\text{eff},T_1}[k]) T \cdots (H_{\text{eff},T_{N_{RF}}}[k]) T]^T \in \mathbb{C}^{N_r \times N_r},
$$

with $H_{\text{eff},T_l}[k] \in \mathbb{C}^{N_r \times N_r}$, and the noise $n[k] = [(n_{T_1}[k]) T \cdots (n_{T_{N_{RF}}}[k]) T]^T \in \mathbb{C}^{N_r \times 1}$ with $n_{T_l}[k] \in \mathbb{C}^{N_r \times 1}$, we have

$$
y_{T_l}[k] = H_{\text{eff},T_l}[k] x[k] + n_{T_l}[k], \quad \forall l.
$$

By substituting (20) into (11), we have

$$
K = \sum_{k=1}^{K} \text{Tr}(E[x[k] x^H[k]]).
$$

To solve (16), we use the following criterion to obtain the optimal fully-digital combiner according to (10), which can be expressed as $W_{\text{opt},H}^T [k] = [W_{\text{RF}}]_l^T T_{opt} [k] \cdots W_{\text{RF}}]_l^T T_{opt} [k] = \mathbb{C}_r \times N_r$. With $W_{\text{opt},T_l}[k] \in \mathbb{C}^{N_{\text{RF}} \times N_r}$, $\forall k$. Furthermore, we can transform (21) into equation (22) below by adding a constant term

$$
2 \sum_{k=1}^{K} \sum_{l=1}^{N_{\text{RF}}} \text{Tr}(F_{S,l}^T T_{opt} [k] W_{\text{RF},T_l}[k] W_{\text{RF},T_l}[k] W_{\text{RF},T_l}[k]),
$$

where $E(y_{T_l}[k] y_{T_l}^H[k]) = H_{\text{eff},T_l}[k] H_{\text{eff},T_l}[k]^H + \sigma_n^2 I_{N_r}$. To solve the $\{W_{\text{BB}}[k]\}_{k=1}^{K}$ and $W_{\text{RF}}$ for minimizing (21), we first use the MMSE criterion to obtain the optimal fully-digital combiner according to (10), which can be expressed as $W_{\text{opt},H}^T [k] = [W_{\text{RF}}]_l^T T_{opt} [k] \cdots W_{\text{RF}}]_l^T T_{opt} [k] \in \mathbb{C}_r \times N_r$

$$
K \sum_{k=1}^{K} \sum_{l=1}^{N_{\text{RF}}} \text{Tr}(W_{\text{RF},T_l}[k] E(y_{T_l}[k] y_{T_l}^H[k]) W_{\text{RF},T_l}[k]),
$$

where $E(y_{T_l}[k] y_{T_l}^H[k]) = H_{\text{eff},T_l}[k] H_{\text{eff},T_l}[k]^H + \sigma_n^2 I_{N_r}$. To solve the $\{W_{\text{BB}}[k]\}_{k=1}^{K}$ and $W_{\text{RF}}$ for minimizing (21), we first use the MMSE criterion to obtain the optimal fully-digital combiner according to (10), which can be expressed as $W_{\text{opt},H}^T [k] = [W_{\text{RF}}]_l^T T_{opt} [k] \cdots W_{\text{RF}}]_l^T T_{opt} [k] \in \mathbb{C}_r \times N_r$

$$
\sum_{k=1}^{K} \sum_{l=1}^{N_{\text{RF}}} \text{Tr}(E(y_{T_l}[k] y_{T_l}^H[k]) W_{\text{RF},T_l}[k]),
$$

(22)

B. Antenna Grouping for Hybrid Precoder in AS

For AS, how to group the transmit/receive antennas, i.e., design $\{S_l\}_{l=1}^{N_{\text{RF}}}$ and $\{T_l\}_{l=1}^{N_{\text{RF}}}$ can further improve the SE performance. At the TX, the optimization of transmit antenna grouping $\{S_l\}_{l=1}^{N_{\text{RF}}}$ can be formulated as the following optimization problem according to (18)

$$
\max_{S_1, \cdots, S_{N_{\text{RF}}}} \sum_{l=1}^{N_{\text{RF}}} \lambda_1^2 (F_{S_l})
$$

s.t. $\cup_{l=1}^{N_{\text{RF}}} S_l = \{1, \cdots, N_r\}$,

$S_i \cap S_j = \emptyset$ for $i \neq j$, $S_i \neq \emptyset \quad \forall l$. (23)

This optimization problem is a combinatorial optimization problem, which requires an exhaustive search to reach the optimal solution. The number of all possible combinations to obtain the optimal solution is

$$
\frac{1}{(N_{\text{RF}})!} \sum_{n=0}^{N_{\text{RF}}} (-1)^{N_{\text{RF}}-n} \binom{N_{\text{RF}}}{n} n! N_r!
$$

According to [35]. For example, when $N_r = 64$ and $N_{\text{RF}} = 4$, the number of all possible combinations can be up to $1.4178 \times 10^{27}$. Therefore, we will design a low-complexity antenna grouping algorithm to maximize (23). Specifically, given $\text{R}_{S_1} = F_{S_1} F_{S_1}^H$, and
Algorithm 2 Proposed Shared-AHC Algorithm to Group Antennas for as

Input: The correlation matrix $R_F = FF^H$, number of antennas $N_t$, number of RF chains $N_{RF}$.  
Output: Antenna grouping results $S_1, \ldots, S_{N_{RF}}$. 

1: $N_{sub} = N_t$, $S_i = \{t\}$ for $i = 1, \ldots, N_t$  
2: while $N_{sub} > N_{RF}$ do  
3: $S_0^i = S_i$ for $i = 1, \ldots, N_{sub}$, $n_{sub} = 1$  
4: for $i = 1 : N_{sub}$ do  
5: if $\exists r_0 \neq i$ s.t. $S_0^i \subseteq S_{r_0}$ then continue  
6: else if $n_{sub}$ then $S_{n_{sub}} = S_0^i$  
7: else $i = 0$  
8: if $i = 0$ then $S_{n_{sub}} = S_i \cup S_j$  
9: else $S_{n_{sub}} = S_i$  
10: end if  
11: end if  
12: $n_{sub} = n_{sub} + 1$  
13: end for  
14: $N_{sub} = n_{sub} - 1$  
15: if $N_{sub} < N_{RF}$ then $S_i = S_0^i$ for $i = 1, \ldots, N_{sub}$  
16: else $N_{sub} = N_{RF}$  
17: end if  
18: end while  
19: if $N_{sub} > N_{RF}$ then sort $S_i$ according to the ascending order of cardinality  
20: for $i = 1 : (N_{sub} - N_{RF})$ do  
21: $j = \arg\max_{l \in \{1, \ldots, N_{sub}\}} g(S_i, S_l)$, $S_i = S_i \cup S_j$  
21: end for  
22: Rearrange the subscript to guarantee that the order of subscripts are from 1 to $N_{RF}$  
23: end if

$R_F = FF^H$, we have $\lambda_1^2(F_{S_i}) = \lambda_1(R_{S_i})$ and the following approximation

\[
\lambda_1(R_{S_i}) \approx \frac{1}{\text{card}(S_i)} \sum_{i=1}^{\text{card}(S_i)} \sum_{j=1}^{\text{card}(S_i)} ||R_{S_i}|_{i,j}|
\]

(24)

which is due to the tight lower bound and upper bound of $\lambda_1(R_{S_i})$ as proven in [24]. Hence, the objective function of (23) becomes $\sum_{l=1}^{N_{RF}} \text{card}(S_l) \sum_{i \in S_l} \sum_{j \in S_l} ||R_F|_{i,j}|$. This is still a combinatorial optimization problem, which requires the exhaustive search with high complexity.

In this paper, we formulate the antenna grouping problem as the clustering analysis problem in machine learning. Since $R_F$ is a correlation metric rather than the distance metric, we focus on the correlation-based clustering approach and propose the shared-AHC algorithm as listed in Algorithm 2. The proposed algorithm is developed from the AHC algorithm [31], and it can divide the antennas into multiple groups connected to different RF chains. Note that the traditional AHC algorithm builds a cluster hierarchy from the bottom up, and it starts by adding all data to multiple clusters, followed by iteratively pair-wise merging these clusters until only one cluster is left at the top of the hierarchy [31]. By contrast, the proposed shared-AHC algorithm simultaneously builds $N_{RF}$ clusters, rather than only one cluster in conventional AHC algorithm. Besides, the pair-wise merging criterion in the proposed algorithm is “shared”, while the conventional AHC algorithm only focuses on the target cluster. To further illustrate this “shared” mechanism, we introduce the metric of mutual correlation $g(S_n, S_m)$ for any two clusters $S_n$ and $S_m$ as

\[
g(S_n, S_m) = \frac{1}{\text{card}(S_n)\text{card}(S_m)} \sum_{i \in S_n, j \in S_m} ||R_F|_{i,j}|, \quad m \neq n.
\]

(25)

In each clustering iteration, we first focus on the cluster $S_n$ and search for a cluster $S_m$ that maximizes $g(S_n, S_m)$ among all possible $S_i$. If the cluster $S_n$ also maximizes $g(S_m, S_i)$ among all possible $S_i$, we merge $S_n$ and $S_m$. Otherwise, the cluster $S_n$ and cluster $S_m$ are not merged, and algorithm goes into the next iteration. Therefore, our proposed algorithm is featured as “shared”, since two clusters mutually share the maximum correlation in the sense of (25).

The steps of the proposed shared-AHC algorithm are elaborated as follows. Step 1 performs the initialization. Step 3 saves the clustering results in the last iteration and initializes the clustering process counter $n_{sub}$. Step 5 considers the special situation that the target cluster is already merged into a former cluster, and step 6 considers the situation that the target cluster is $S_{n_{sub}}$ and not merged into any of the former clusters. To maximize the correlation $g(S_i, S_l)$ for the target cluster $S_i$, the operation $i = \arg\max_{l \in \{1, \ldots, N_{sub}\}} g(S_i, S_l)$ in step 7 will search for the cluster $S_l$ from the clusters that have not been searched, i.e., $\{S_j\}_{j=1}^{n_{sub}}$. The operation $i = \arg\max_{l \in \{1, \ldots, N_{sub}\}} g(S_i, S_l)$ in step 7 further judges whether $S_i$ also has the maximum mutual correlation for the chosen $S_l$ or not. $i = 0$ in step 8 indicates this judge holds, then clusters $S_i$ and $S_j$ are merged. Otherwise, these two clusters will not be merged (step 9). After processing $S_i$, the cluster counter $n_{sub}$ is increased by one, and the next target cluster will be processed (step 12). After the loop including steps 4-13 finishes, if the resulting number of clusters $N_{sub} < N_{RF}$ (step 15), the iteration stops and the clustering result of the last iteration will be considered, i.e., $S_i = S_0^i$ for $i = 1, \ldots, N_{sub}$. Otherwise, we continue the iteration (step 16). Steps 19-23 ensure the result $N_{sub} = N_{RF}$. If $N_{sub} > N_{RF}$, the $(N_{sub} - N_{RF})$ clusters with $(N_{sub} - N_{RF})$ smallest cardinality are merged within the rest $N_{RF}$ clusters (steps 19-21). Step 22 guarantees that the subscripts of clustering result match the notation of RF chains.

Note that although the antenna grouping $\{S_i\}_{i=1}^{N_{RF}}$ designed by Algorithm 2 is based on the instantaneous CSI $H[k]$, $\{S_i\}_{i=1}^{N_{RF}}$ mainly depends on the steering vectors having the first $N_s$ largest path gains for massive MIMO with large $N_t$ (Proposition 4). On the other hand, for time-varying MIMO channels, the variation rates for channel angles and the absolute values of channel gains are usually much slower.
than that for channel gains [41]. This indicates that once \( \{ S_l \}_{l=1}^{N_{\text{RF}}} \) is determined, it can remain unchanged for a long period of time with negligible performance loss. The proof for Proposition 4 is provided as follows.

**Proposition 4:** For massive MIMO with large \( N_r \), the correlation matrix \( \mathbf{R}_F \) for antenna grouping only depends on the steering vectors associated with the first \( N_r \) largest path gains.

**Proof:** For massive MIMO, the transmit/receive steering vectors are asymptotic orthogonal, i.e., \( \lim_{N_r \to \infty} \mathbf{A}_r^H \mathbf{A}_r = \mathbf{I}_{N_r N_{\text{ray}}} \) and \( \lim_{N_r \to \infty} \mathbf{A}_t^H \mathbf{A}_t = \mathbf{I}_{N_t N_{\text{ray}}} \) [8]. Furthermore, we assume an ideal pulse-shaping \( p(t) = \delta(t) \) and \( |\alpha_{1,2}| > |\alpha_{1,2}| > \cdots > |\alpha_{N_r N_{\text{ray}}}| \) for ease of analysis. So the SVD of \( \mathbf{H}[k] \) in (6) can be written as \( \mathbf{U}[k] = [\mathbf{A}_r \mathbf{U}_r] \), \( \Sigma[k] = \text{blkdiag}(|\mathbf{P}[k]|, \mathbf{0}_{(N_r - N_{\text{ray}}) \times (N_r - N_{\text{ray}})}) \), and \( \mathbf{V}[k] = \text{blkdiag}(e^{j\mathbf{P}[k] \mathbf{I}_{N_r - N_{\text{ray}}}} \mathbf{A}_t \mathbf{V}_t) \), where \( \mathbf{U}_r \in \mathbb{C}^{N_r \times (N_r - N_{\text{ray}})} \) and \( \mathbf{V}_t \in \mathbb{C}^{N_t \times (N_t - N_{\text{ray}})} \), respectively. \( \mathbf{U}_r \) and \( \mathbf{V}_t \) are semi-unitary matrices respectively satisfying \( \text{Col} \mathbf{U}_r = \text{Col} \mathbf{A}_t \mathbf{U}_r \) and \( \text{Col} \mathbf{U}_t = \text{Col} \mathbf{A}_t \mathbf{U}_t \). Define the matrix \( \mathbf{P}[k] = \text{blkdiag}(e^{j\mathbf{P}[k] \mathbf{I}_{N_r - N_{\text{ray}}}} \mathbf{A}_t \mathbf{V}_t) \), \( \mathbf{P}_r = \text{blkdiag}(e^{j\mathbf{P}[k] \mathbf{I}_r \mathbf{K}_T}, e^{-j\mathbf{P}[k] \mathbf{I}_r \mathbf{K}_T}, \ldots, e^{-j\mathbf{P}[k] \mathbf{I}_r \mathbf{K}_T}) \), and \( \mathbf{G} = \text{blkdiag}(e^{j\mathbf{P}[k] \mathbf{I}_r \mathbf{K}_T}, e^{-j\mathbf{P}[k] \mathbf{I}_r \mathbf{K}_T}, \ldots, e^{-j\mathbf{P}[k] \mathbf{I}_r \mathbf{K}_T}) \). Define the matrix consisting of the steering vectors associated with the first \( N_r \) largest singular values as \( \mathbf{A}_{r, \text{max}} N_r = [\mathbf{A}_{r, 1}, \ldots, \mathbf{A}_{r, 1}] \), we have \( \mathbf{P}_r \mathbf{F}_r[k] = \mathbf{F}_r[k] = \mathbf{A}_{r, \text{max}} N_r \). Therefore, \( \mathbf{R}_F = \mathbf{F}_r \mathbf{F}_r^H = \mathbf{K} \mathbf{A}_{r, \text{max}} N_r \mathbf{A}_{r, \text{max}} N_r^H \), is to say, \( \mathbf{R}_F \) only depends on the steering vectors associated with the first \( N_r \) largest path gains.

**C. Antenna Grouping for AS on Hybrid Combiner**

Furthermore, we consider the antenna grouping for AS at the RX. To decouple \( \mathbf{w}_{\text{RF}, T_i} \) and \( \{ \mathbf{w}_{\text{BB}, T_i}[k] \}_{k=1}^{K} \) in (22), we rewrite the problem (11) as

\[
\min_{\{ \mathbf{w}_{\text{RF}, T_i}[k] \}_{k=1}^{K}} \sum_{k=1}^{K} \sum_{l=1}^{N_{\text{RF}}} \| \mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]]^\dagger (\mathbf{w}_{\text{RF}, T_i}[k] - \mathbf{w}_{\text{BB}, T_i}[k]) ||_F \tag{26}
\]

s.t. \( \mathbf{w}_{\text{RF}, T_i} \in \mathbf{R}_{\text{RF}, T_i} \),

where \( \mathbf{R}_{\text{RF}, T_i} \) is a set of feasible RF combiner satisfying the CMC. Given the RF combiner \( \mathbf{w}_{\text{RF}, T_i} \), the objective function (26) can be rewritten as

\[
\min_{\{ \mathbf{w}_{\text{BB}, T_i}[k] \}_{k=1}^{K}} \sum_{k=1}^{K} \| \mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]]^\dagger (\mathbf{w}_{\text{RF}, T_i}[k] - \mathbf{w}_{\text{RF}, T_i}[k]) ||_F \tag{27}
\]

for \( 1 \leq l \leq N_{\text{RF}} \). For (27), the optimal baseband combiner can be obtained by weighted LS as

\[
\mathbf{w}_{\text{BB}, T_i}[k] = (\mathbf{w}_{\text{RF}, T_i}[k] \mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]] \mathbf{w}_{\text{RF}, T_i}[k])^{-1} \mathbf{w}_{\text{RF}, T_i}[k] \mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]] \mathbf{w}_{\text{opt}, T_i}[k]. \tag{28}
\]

By substituting (28) into (22), we obtain

\[
\sum_{k=1}^{K} \sum_{l=1}^{N_{\text{RF}}} \text{Tr}(\mathbf{w}_{\text{RF}, T_i}[k]\mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]]\mathbf{w}_{\text{opt}, T_i}[k]) - \mathbf{w}_{\text{RF}, T_i}[k]\mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]]\mathbf{w}_{\text{RF}, T_i}[k]\mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]]w_{\text{RF}, T_i}[k] - \mathbf{w}_{\text{RF}, T_i}[k]\mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]]\mathbf{w}_{\text{RF}, T_i}[k] \tag{29}
\]

Note that minimizing (29) is equivalent to maximizing the following function

\[
\sum_{k=1}^{K} \sum_{l=1}^{N_{\text{RF}}} \text{Tr}(\mathbf{w}_{\text{RF}, T_i}[k]\mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]]\mathbf{w}_{\text{RF}, T_i}[k]\mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]]\mathbf{w}_{\text{RF}, T_i}[k]) \tag{30}
\]

Furthermore, we consider

\[
\mathbf{E}[y_{T_i}[1]y_{T_i}^H[1]] \approx \cdots \approx \mathbf{E}[y_{T_i}[K]y_{T_i}^H[K]] \approx \mathbf{E}[y_{T_i}[y_{T_i}^H]], \tag{31}
\]

Note that the approximation error in (31) can be ignored in large antennas regime as proven in Appendix D. By substituting (31) into (30), we can obtain, (32) shown at the bottom of this page. The maximum of (32) is \( \sum_{l=1}^{N_{\text{RF}}} \lambda_1^2(\mathbf{w}_{\text{RF}, T_i}) \) when \( \mathbf{w}_{\text{RF}, T_i} = \frac{1}{\sqrt{N_{\text{RF}}}} \exp(j \angle (\mathbf{u}_{T_i}, 1)) \) as discussed in Section IV-A. Therefore, the optimization of \( \{ \mathbf{T}_i \}_{i=1}^{N_{\text{RF}}} \) can be formulated as

\[
\min_{\mathbf{T}_1, \ldots, \mathbf{T}_{N_{\text{RF}}}} \sum_{l=1}^{N_{\text{RF}}} \lambda_1^2(\mathbf{w}_{\text{RF}, T_i}) \tag{33}
\]

s.t. \( \mathbf{T}_i = \{ 1, \ldots, N_r \}, \mathbf{T}_i \cap \mathbf{T}_j = \emptyset \) for \( i \neq j, \mathbf{T}_i \neq \emptyset \forall l \).

Similar to (24), we further obtain \( \lambda_1(\mathbf{R}_{\text{RF}, T_i}) = \lambda_1(\mathbf{R}_{\text{RF}, T_i}) \) and

\[
\lambda_1(\mathbf{R}_{\text{RF}, T_i}) \approx \frac{1}{\text{card}(\mathbf{T}_i)} \sum_{t=1}^{\text{card}(\mathbf{T}_i)} \sum_{j=1}^{\text{card}(\mathbf{T}_i)} \| \mathbf{R}_{\mathbf{T}_i}[i,j] \| \tag{34}
\]

Note that (33) is more difficult to reach than (23) because of the existence of the weight matrix \( \mathbf{E}[y_{T_i}[k]y_{T_i}^H[k]]^\dagger \).
where $R_{T_{k}} = W_{T_{k}}W_{T_{k}}^{H}$ and $R_{W} = WW^{H}$. Finally, the antenna grouping $\{T_{k}\}_{k=1}^{K} \{c\}_{c=1}^{C}$ at the RX can be obtained using Algorithm 2 by replacing the input parameters $R_{F}$, $N_{r}$, and $N_{r}^{RF}$ for the TX with $R_{W}$, $N_{r}$, and $N_{r}^{RF}$ for the RX. By contrast, the antenna grouping solution in [24] considers the hybrid transmit array but the fully-digital receive array, and how to group the antennas for hybrid receive array is not explicitly specified.

V. PERFORMANCE EVALUATION

In this section, we will investigate the SE, EE, and BER performance of the proposed hybrid precoder/combiner design. In simulations, the pulse shaping filter is $p(\tau) = \delta(\tau)$, the length of cyclic prefix is $D = 64$, and the number of subcarriers is $K = 512$. The carrier frequency is $f_{c} = 30$ GHz, the bandwidth is $B = 500$ MHz, the path delay is uniformly distributed in $[0, DT_{s}]$ ($T_{s} = 1/B$ is the symbol period), the number of clusters is $N_{c1} = 8$, the azimuth/elevation angle spread of each cluster is $7.5^{\circ}$ for both AoD and AoA, and there are $N_{ray} = 10$ rays within each cluster. Both the TX and RX adopt $8 \times 8$ hybrid UPA with $N_{r}^{RF} = N_{r}^{RF} = 4$ unless otherwise stated. The number of data stream is $N_{s} = 3$. Four types of classical FS patterns shown in Fig. 3 will be investigated, where the antennas with the same color are connected to the same RF chain for constituting a subarray. The channel estimation overhead is not considered in the evaluation.

State-of-the-art solutions will be compared as benchmarks. 1) **Optimal fully-digital** scheme considers the fully-digital MIMO system, where the SVD-based precoder/combiner is adopted as the performance upper bound. 2) Since the OMP-based spatially sparse precoding [17] is proposed for narrowband channels, we consider a broadband version that can simultaneously design the RF precoder/combiner for all subcarriers, denoted by **simultaneous OMP (SOMP)** scheme. 3) **Discrete Fourier transform (DFT) codebook** scheme [24] designs the RF precoder/combiner from the DFT codebook instead of steering vectors codebook in SOMP scheme [42]. 4) **Covariance eigenvalue decomposition (EVD)** scheme focuses on the hybrid precoder design based on the EVD of the channel covariance matrix $R_{cov} = \frac{1}{K} \sum_{k=1}^{K} H[k]H[k]$ and assumes the fully-digital receive array. To extend this scheme to hybrid receive arrays, the RF combiner is designed using the same processing as the RF precoder by replacing $R_{cov}$ with $\tilde{R}_{cov} = \frac{1}{K} \sum_{k=1}^{K} H[k]H[k]$, and the digital combiner is designed based on MMSE criterion.

A. SE and BER Performance Evaluation

In Fig. 4, we compare the SE performance of different hybrid precoder schemes, where the system adopts the hybrid transmit array and fully-digital receive array. For the hybrid transmit array, FCA and PCS are investigated in Fig. 4(a) and (b), respectively. Besides, the practical phase shifters with resolutions $Q = 3$ and $Q = 1$ are considered, and the ideal phase shifters without quantization, denoted by $Q = \infty$, is also compared to examine the impact of $Q$ [33]. For the FCA, Fig. 4 (a) shows that the proposed PCA-based solution and the covariance EVD-based solution have the similar performance, and our proposed solution has the considerable superiority over conventional DFT codebook-based and SOMP-based solutions. This is because that our proposed solution exploits the principal components of the common column space of $\{H[k]\}_{k=1}^{K}$ to design the analog precoder $F_{RF}$. By contrast, the analog precoders designed by the SOMP-based and DFT codebook-based solutions are based on the codebooks, whose entries are limited to the steering vector form. This kind of inflexible RF precoder designs would lead to the poor performance. Additionally, for the proposed hybrid precoder scheme, we can observe the performance gap between adopting $Q = \infty$ and $Q = 3$ is negligible, but that between adopting $Q = 3$ and $Q = 1$ is around 3 (bps/Hz) at
high SNR conditions. As for the PCS, we only investigate the SE performance under $Q = 3$ in Fig. 4 (b), which manifests that our proposed scheme is as good as the state-of-the-art covariance EVD-based hybrid precoder design for different FS patterns and AS. Finally, the performance gain achieved by the proposed antenna grouping algorithm for AS over several typical FS patterns is more than 1 (bps/Hz) at high SNR conditions. So the advantage by using AS is self-evident.

Fig. 5 examines the SE performance of different hybrid precoder/combiner schemes, where both the TX and RX adopt the hybrid array, and the phase shifters under different $Q$ are considered. From Fig. 5 (a), we can observe that the proposed solution is superior to other three state-of-art solutions, and the performance of covariance EVD-based scheme becomes poor. When expanding to RX with hybrid combiner, the covariance EVD-based scheme performs poorly because [24] initially considers the fully-digital combiner and its extension to hybrid combiner by using the channel reciprocity suffers from a large performance loss. While in our proposed scheme, both the hybrid precoder and hybrid combiner are jointly designed based on PCA framework so the better SE performance can be achieved. Especially, for the proposed solution, the performance gap between adopting $Q = \infty$ and $Q = 3$ is negligible, but that between adopting $Q = 3$ and $Q = 1$ is larger than 5 (bps/Hz) at high SNR conditions. For the PCS under $Q = 3$, Fig. 5 (b) shows the superiority of our scheme over state-of-the-art covariance EVD-based scheme for different FS patterns and AS. This is because the antenna grouping scheme in [24] is based on the greedy search so that the local optimal solution may be acquired. This could lead to the extremely unbalanced antenna grouping case that no antenna is assigned to one RF chain, and thus the SE performance is degraded. By contrast, the proposed antenna grouping algorithm introduces the mutual correlation metric (25), which can effectively avoid this issue. Besides, Fig. 4 (b) also indicates that at least 5 (bps/Hz) SE gains can be achieved by the AS over the FS, since the proposed shared-AHC algorithm can group the antennas adapted to the CSI for the enhanced SE performance.

In Fig. 6, we compare the BER performance of different hybrid precoder/combiner schemes, where the same channel parameters as considered in Fig. 5 are used, and 16 QAM is adopted for transmission. From Fig. 6, similar conclusions to those observed for Fig. 5 can be obtained. In particular, it can
be seen that the AS by using our proposed antenna grouping scheme significantly outperforms four typical FS patterns.

**B. EE Performance Evaluation**

To further explore the performance of different array structure, we analyze the EE performance of different array structure in this subsection. The EE metric is defined as $\eta = R B_s / P$, where $B_s$ is the transmission bandwidth, $R$ is the SE in (3), and $P$ is the total power consumption of the antenna arrays. Here $P$ depends on the following two factors. Firstly, FCA and PCS have the different power consumption due to the different numbers of phase shifters required, where the FCA requires $N_{PS} = N_t N_{RF} = 64 \times 4$ phase shifters, but the PCS only requires $N_{PS} = N_t = 64$ phase shifters. Secondly, passive and active arrays have different power consumption, since they have different architectures. From Fig. 7 (a) and (b), we can observe that both of them consist of analog-digital/digital-analog converters (AD/DA), low noise amplifiers (LNA), power amplifiers (PA), local oscillators (LO), duplexers or switches (DPX/S), and mixers etc. However, they have the different numbers of PAs/LNAs. For passive antennas, the number of PAs/LNAs is the same as that of RF chains. While for active antennas, the number of PAs/LNAs is the same as that of antennas. This difference can lead to the different power consumption. The power values of electronic components that dominate the power consumption are listed as follows: $P_{PS} = 15$ mW for 3-bit phase shifter [37], $P_{AD} = P_{DA} = 200$ mW for AD/DA [37], $P_{mix} = 39$ mW for mixer [38], $P_{PA} = 138$ mW for PA [39], $P_{LNA} = 39$ mW for LNA [39], $P_{LO} = 5$ mW for LO [37], and $P_{syn} = 50$ mW for synchronizer [40]. Therefore, the power consumption for FCA and PCS adopting active antenna architecture can be respectively calculated as

$$P_{FCA}^a = N_t N_{RF} (P_{DA} + P_{mix} + P_{LO} + P_{PA}) + N_t N_{PS} + 2P_{syn} + N_r N_{RF} (P_{AD} + P_{mix} + P_{LO} + P_{LNA}) + P_{PS} + N_r N_{RF} P_{PS}$$

$$P_{PCS}^a = N_t N_{RF} (P_{DA} + P_{mix} + P_{LO} + P_{PA}) + N_t N_{PS} + 2P_{syn} + N_r N_{RF} (P_{AD} + P_{mix} + P_{LO} + P_{LNA}) + P_{PS} + N_r N_{PS} + N_r N_{LNA}.$$ 

Moreover, the power consumption for FCA and PCS adopting active antenna are

$$P_{FCA}^a = N_t N_{RF} (P_{DA} + P_{mix} + P_{LO}) + N_r N_{PS} + 2P_{syn} + N_r N_{RF} (P_{AD} + P_{mix} + P_{LO}) + N_r N_{RF} P_{PS} + N_r N_{LNA}.$$ 

Besides, for fully-digital array (FDA) as shown in Fig. 2 (c), the power consumption is

$$P_{FDA} = N_t (P_{PA} + P_{mix}) + 2P_{syn} + N_r (P_{LNA} + P_{AD} + P_{mix} + P_{LO}).$$

In Fig. 8, we compare the EE performance of different hybrid precoder/combiner schemes under $Q = 3$, where passive and active antenna architectures are investigated in Fig. 8 (a) and (b), respectively. For passive antenna architecture examined in Fig. 8 (a), the EE performance of PCS by using the proposed PCA-based hybrid precoder/combiner scheme outperforms that of FCA by using the proposed and other state-of-the-art schemes. The reason is that PCS adopts a much smaller number of phase shifters than FCA, though the SE performance achieved by PCS is inferior to that achieved by FCA. Moreover, AS obviously outperforms the other FS patterns in SE, and it consumes the very similar power with the other FS patterns. Therefore, AS outperforms other four types of FS patterns in EE. Note that the optimal fully-digital scheme has the worst EE performance, since the numbers of power-consuming PAs, LNAs, ADs/DAs, mixers are proportional to that of antennas.

---

1DPX/S is used to transmit/receive signals by sharing the same antenna hardware. When working in transmitting (receiving) mode, the DPX/S ensures the transmit/receive) signal delivered from PA (antennas) to antennas (LNA). So the power consumption of DPX/S can be ignored since the switching duration between the transmitting and receiving mode is neglected. Besides, the power consumption of switches when the antenna grouping patterns for AS changes is also ignored.
Fig. 8. EE performance comparison of different hybrid precoder/combiner schemes based on different antenna architectures with $Q = 3$: (a) Passive antenna; (b) Active antenna.

For active antennas investigated in Fig. 8 (b), the EE advantage for different FS patterns by using the proposed hybrid precoder/combiner scheme over the FCA with several typical hybrid precoder/combiner schemes and fully-digital array with the optimal precoder/combiner scheme is not obvious. This is because the active antenna architecture requires the power-hungry PAs/LNAs for each antenna. Meanwhile, the advantage of the reduced power consumption benefiting from FS structure is greatly weakened by its disadvantage in SE performance when compared with FCA. Finally, the EE performance of AS with the proposed hybrid precoder/combiner scheme still has the considerable advantage over the other schemes. This observation reveals the appealing advantage of AS in practical situation when both the power consumption and SE should be well balanced.

C. Computational Complexity and Robustness of the Proposed Shared-AHC Algorithm

With respect of the antenna grouping, the computational complexity of the shared-AHC algorithm for the proposed PCA-based method and the greedy algorithm for the covariance EVD method [24] are compared. However, their computational complexity is difficult to be accurately calculated. On the one hand, both two algorithms have the selection statements of “if” and “else”, and the complexity can be different for different selections. On the other hand, the total number of iterations for the shared-AHC algorithm is adaptive. Therefore, Fig. 9 (a) compares the practical runtime of these two algorithms instead, where the simulations are based on the software MATLAB 2016a and the hardware Intel Core i7-7700 CPU and 16 GB RAM. Fig. 9 (a) shows the mean and standard deviation of the runtime of two antenna grouping algorithms, and their similar run time versus different sizes of transmit UPA can be observed.

Fig. 9 (b) investigates the robustness of the shared-AHC algorithm to time-varying channels. In simulations, we consider the time-varying block-fading channels, where each time block consists of 10 OFDM symbols, the channels of different OFDM symbols from the same time blocks are correlated, but the channels from different time blocks are mutually independent. For time-varying channels, the variation rate of channel AoAs/AoDs is much slower than that of the channel gains [41]. So we consider that the channels of different OFDM symbols in the same time block share the same AoAs/AoDs and the modulus values of channel gains, but
perturbation error $N_{\text{per}}[k]$ follows the independent and identically distributed complex Gaussian distribution $CN(0, \sigma^2_{\text{per}})$. From Fig. 10 (a), we can observe that both the proposed scheme and covariance EVD-based approach have the similar robustness to channel perturbation. This is because both our proposed scheme and covariance EVD scheme can extract the correct frequency-flat component from the frequency-selective channels with perturbation. From Fig. 10 (b), we can observe that both the proposed scheme and SOMP-based approach have the similar robustness to channel perturbation and outperform other schemes. Note that the SOMP-based approach requires the full knowledge of steering vectors, which can be impractical. When the full knowledge of steering vectors is inaccessible (SOMP-based scheme reduces to the DFT codebook scheme), the performance degrades drastically. By contrast, our proposed scheme does not require the knowledge of steering vectors and have the robustness performance to channel perturbation.

VI. CONCLUSION

In this paper, we proposed a hybrid precoding scheme based on PCA for broadband mmWave massive MIMO systems. We first designed a low-dimensional frequency-flat precoder/combiner from the optimal frequency-selective precoder/combiner based on PCA for fully-connected array. Moreover, we extended the proposed PCA-based hybrid precoder/combiner design to the partially-connected subarray given the antenna grouping pattern. For the adaptive subarray, we further proposed the shared-AHC algorithm inspired by cluster analysis in the field of machine learning to group the antennas for the further improved SE performance. Finally, the better SE, BER, and EE performance of the proposed hybrid precoder/combiner solution over state-of-the-art solutions was verified in simulations.

APPENDIX A

PROOF OF LEMMA 1

To start with, we make the following system approximation. \textbf{Approximation 1: We assume that the hybrid precoder $\mathbf{F}_{\text{RF}}\mathbf{F}_{\text{BB}}[k]$ can be sufficiently “close” to the optimal fully-digital precoder $\mathbf{F}_{\text{FD}}^{\text{opt}}[k] = \mathbf{F}_{\text{RF}}\mathbf{F}_{\text{BB}}[k]$, $\forall k$, under the given system model and parameters (e.g., $N_t, N_r, N_{RF}, N_s, N_{\text{cl}}, N_{\text{ray}}, \ldots$). Define $\Sigma[k] = \text{blkdiag}(\Sigma_1[k], \Sigma_2[k])$, where $\Sigma_1[k] = [\Sigma[k]; 1, N_s, \ldots]$ and $\mathbf{V}[k] = [\mathbf{F}_{\text{FD}}^{\text{opt}}[k] \mathbf{V}_2[k]]$ in (6), $\forall k$, this “closeness” is defined based on the following two equivalent approximations: (1)}

1) The eigenvalues of the matrix $I_{N_s} - F_{\text{FD}}^{\text{opt}}[k] F_{\text{RF}} F_{\text{BB}}[k] F_{\text{BB}}^H[k] F_{\text{RF}}^H[k]$ are small. In this case, it can be equivalently stated as $F_{\text{FD}}^{\text{opt}}[k] F_{\text{RF}} F_{\text{BB}}[k] \approx I_{N_s}$.

2) The singular values of the matrix $\mathbf{V}[k] F_{\text{RF}} F_{\text{BB}}[k]$ are small, i.e., $\mathbf{V}[k] F_{\text{RF}} F_{\text{BB}}[k] \approx 0$.

According to (6), the objective function of problem (4) can be written as

$$\sum_{k=1}^{K} \log_2(\det(I_{N_s} + \frac{1}{\sigma_n^2} \Sigma^2[k] \mathbf{V}[k] F_{\text{RF}} F_{\text{BB}}[k] F_{\text{RF}}^H[k])) - \sum_{k=1}^{K} \log_2(\det(I_{N_s} + \frac{1}{\sigma_n^2} \Sigma^2[k] \mathbf{V}[k] F_{\text{RF}} F_{\text{BB}}[k] F_{\text{RF}}^H[k])).$$

$$\sum_{k=1}^{K} \log_2(\det(I_{N_s} + \frac{1}{\sigma_n^2} \Sigma^2[k] \mathbf{V}[k] F_{\text{RF}} F_{\text{BB}}[k] F_{\text{RF}}^H[k])), \quad (35)$$
Following the similar derivation for formula (12) in [17], we define (*), shown at the bottom of this page. Based on the above definition, (35) can be approximated as

$$\sum_{k=1}^{K} \log_2(\det(I_N + \frac{1}{\sigma_n^2} [\Sigma_1^2[k] \ 0 \ 0 \ 0 \ \Sigma_2^2[k]])^{1/2}) = (I + F_{D} + F_{N} F_{B} B[k]) \cdot (I + H_{F} F_{B} B[k])^{-1}$$

(36)

According to Schur complement identity for matrix determinants, (36) is equivalent to

$$\sum_{k=1}^{K} \log_2(\det(I_N) + \frac{1}{\sigma_n^2} \Sigma_1^2[k] M_{11}[k]) + \log_2(\det(I_N - M_{11}[k])^{-1})$$

$$+ \frac{1}{\sigma_n^2} \Sigma_1^2[k] M_{22}[k]$$

(37)

According to Approximation 1 (2), $M_{21}[k]$, $M_{12}[k]$, and $M_{22}[k]$ are approximately 0, so (37) can be approximated as

$$\sum_{k=1}^{K} \log_2(\det(I_N) + \frac{1}{\sigma_n^2} \Sigma_1^2[k] F_{D} F_{B} F_{B}[k])$$

(38)

where the equation holds when Approximation 1 holds. Based on $I + BA = (I + B)(I - (I + B)^{-1}B$ ($I - A)$) with the definition $B = \Sigma_2^2[k]$, the equation can be simplified as

$$\sum_{k=1}^{K} \log_2(\det(I_N) + \frac{1}{\sigma_n^2} \Sigma_1^2[k])$$

$$+ \frac{1}{\sigma_n^2} \Sigma_1^2[k] I_N^{-1}$$

$$- F_{D} F_{B} F_{B}[k] F_{D} F_{B} F_{B}[k]$$

(39)

Approximation 1 (I) implies the eigenvalues of matrix $(I_N + \frac{\Sigma_2^2[k]}{\sigma_n^2})^{-1}$ are small. Therefore, the water-filling power allocation coefficients can be ignored. Specifically, the equivalent baseband precoder is $F_{B}[k] = [V[k]]_{1:N_i}$. Hence, $F_{B}[k]$ is a unitary or semi-unitary matrix. Therefore, the two conditions separate.

When $N_s = N_i F_{N}$, $F_{B}[k]$ is a unitary matrix. Therefore, (42) can be simplified as

$$\sum_{k=1}^{K} \log_2(\det(I_N) + \frac{1}{\sigma_n^2} \Sigma_1^2[k])(I_N - M_{11}[k])^{-1}$$

$$+ \frac{1}{\sigma_n^2} \Sigma_1^2[k] I_N^{-1}$$

$$- F_{D} F_{B} F_{B}[k] F_{D} F_{B} F_{B}[k]$$

(40)

where the equation holds when Approximation 1 holds. Based on the high SNR approximation $(I_N + \frac{\Sigma_2^2[k]}{\sigma_n^2})^{-1} \approx I_N$, (40) can be further approximated as

$$\sum_{k=1}^{K} \log_2(\det(I_N) + \frac{1}{\sigma_n^2} \Sigma_1^2[k])) - (N_s - \frac{\Sigma_2^2[k]}{\sigma_n^2} F_{D} F_{B} F_{B}[k])$$

(41)

where this equation holds at high SNR conditions. Therefore, the optimization problem (4) can be approximated as (9).

Appendix B

Proof of Proposition 1

The SVD of $F_{N}$ can be written as $U_{F_{N}}[\Sigma_{F_{N}}] U_{F_{N}}^{H} = \bar{U}_{F_{N}}[\Sigma_{F_{N}}] U_{F_{N}}^{H}$, where $U_{F_{N}}[\Sigma_{F_{N}}] U_{F_{N}}^{H} = \bar{U}_{F_{N}}[\Sigma_{F_{N}}] U_{F_{N}}^{H}$, and $U_{F_{N}} = [U_{F_{N}}]_{1:N_i N_{i} F_{N}}$. The formula (7) can be further expressed as $F_{B}[k] = V_{F_{N}}[U_{F_{N}}^{H}] F_{B}[k]$. Hence, the objective function in (9) can be written as

$$\sum_{k=1}^{K} \|F_{D}^{opt} H[k] U_{F_{N}}^{H} V_{F_{N}}^{H} F_{B}[k]|_{F}^{2}$$

(42)

Appendix C

According to previous work [34], unitary constraints offer a close performance to the total power constraint and provide a relatively simple form of solution. Therefore, we consider the condition under unitary power constraints instead. Therefore, the water-filling power allocation coefficients can be ignored. Specifically, the equivalent baseband precoder is $F_{B}[k] = [V[k]]_{1:N_i}$. Hence, $F_{B}[k]$ is a unitary matrix or semi-unitary matrix depending on $N_s = N_i F_{N}$ or $N_s < N_i F_{N}$. Therefore, in the following part, we discuss the two conditions separately.

When $N_s = N_i F_{N}$, $F_{B}[k]$ is a unitary matrix. Therefore, (42) can be simplified as

$$\sum_{k=1}^{K} \|F_{D}^{opt} H[k] \bar{U}_{F_{N}}^{H} V_{F_{N}}^{H} F_{B}[k]|_{F}^{2}$$

(43)

Since $U_{F_{N}}$ and $U_{F}$ are semi-unitary and unitary matrix, (43) reaches the maximum only when $U_{F_{N}} = [U_{F}]_{1:N_i}$. Therefore, (42) can be simplified as

$$\sum_{k=1}^{K} \|F_{D}^{opt} H[k] U_{F_{N}}^{H} V_{F_{N}}^{H} F_{B}[k]|_{F}^{2}$$

(44)
Moreover, the rank of $F_{RF}$ is $N_{RF}^r$. Hence, the suboptimal RF precoder can be expressed as $F_{RF} = \frac{1}{\sqrt{\nu}}\exp(j\angle((U_{RF}^{opt})^H\cdot1_{N_{RF}^r}))$.

When $N_s < N_{RF}^r$, $F_{BB}[k]$ is a semi-unitary matrix. Given the SVD $F_{BB}[k] = U_{BB}[k]I_{N_s}\ 0^{N_{RF}^r}$, $V_B[k] = U_{BB}^H[k]$, the conclusion of Proposition 2 can be simplified as

$$K \sum_{k=1}^K \text{Tr}(F_{RF}^{opt}) [k]U_{RF}V_{RF}U_{BB}[k]|\text{blkdiag}(I_{N_s}, 0)U_{BB}^H[k]$$

$$\times V_B[k]$$

(44)

It is obvious that the solution maximizing (43) also maximizing (44). Therefore, following the similar derivation of (43), the conclusion of $F_{RF} = \frac{1}{\sqrt{\nu}}\exp(j\angle((U_{RF}^{opt})^H\cdot1_{N_{RF}^r}))$ is easy to be reached.

**APPENDIX C**

**PROOF OF PROPOSITION 2**

Substituting $W_{BB}^{WLS}[k]$ (14) into the objective function of (13), we obtain

$$K \sum_{k=1}^K \frac{1}{2}(U_{RF}W_{BB}[k] - W_{RF}W_{BB}[k])$$

where $W_{RF} = \frac{1}{\sqrt{\nu}}\exp(j\angle((U_{RF}^{opt})^H\cdot1_{N_{RF}^r}))$.

We can find a unitary matrix $U[k] \in C_{N_r \times N_r}$ satisfying $U[k]B[k] = U[k]W_{RF}$, thus $U[k]W_{RF} = U[k]B[k] = U[k]W_{RF}$, Hence, a suboptimal solution to problem (47) is $W_{RF} = \frac{1}{\sqrt{\nu}}\exp(j\angle((U_{RF}^{opt})^H\cdot1_{N_{RF}^r}))$

(48)

**APPENDIX D**

**PROOF OF (31)**

By substituting (6) and (7) into (19), we obtain $H_{eff}[k] = H[k]F_{RF}F_{BB}[k] = U[k]U[k][\bar{\Sigma}[k]]V[k]$.

$$\times [V[k]_{\cdot 1:1:1}, I_{N_s}A[k]]$$

The effective channel can be further written as

$$H_{eff}[k] = U[k][U[k][\bar{\Sigma}[k]]V[k]_{\cdot 1:1:1}, I_{N_s}A[k]]$$

(49)

In large antenna, $U[k] = I$ and $\bar{\Sigma}[k] = \Sigma[k]$. Therefore, the covariance matrix of $y_T[k]$ can be expressed as

$$E[y_T[k][y_T[k]^H] = H_{eff}[k] + \sigma_n^2 I_{N_{sub}}$$

(50)

Considering (20), the effective covariance matrix $H_{eff,T}[k] = [A_T[k]_{\cdot 1:1:N_s} + \sigma_n^2 I_{N_{sub}}]$.

Therefore, the covariance matrix of $y_T[k]$ can be expressed as

$$E[y_T[k][y_T[k]^H] = H_{eff,T}[k] + \sigma_n^2 I_{N_{sub}}$$

(51)

Since $|P[k]|$ remains unchanged for different $k$, $E[y_T[k][y_T[k]^H]$ is irrelevant with $k$ for large $N_t$. Therefore, (31) is valid in the regime of very large number of antennas, and this approximation error can usually be negligible for mmWave massive MIMO with large number of antennas.
